(54) Title: HOOK FASTENERS AND METHODS OF MANUFACTURE			
(57) Abstract			
<p>This invention is a hook fastener member (18) having rows of molded hook shaped fastener elements (114) that lie in planes aligned with the rows, with generally planar plate portions (118) at the outermost ends (117) of at least some of the fastener elements (114), the plate portions (118) lying generally parallel to the base (112) of the fastener member (18). The plate portions (118) can enhance engagement of the hook fastener members with mating loop fastener members (22), particularly with low loft non-woven loop fastener members. A method of making fastener members (18) is provided. Molten resin is extruded, and applied to a molding roller (50), creating preforms. The outermost portions of at least some of the preforms are flattened, thereby forming generally plate shaped portions. Disposable absorbent garments (10) advantageously incorporate the hook fastener members (18).</p>

HOOK FASTENERS AND METHODS OF MANUFACTUREBackground of the Invention

The invention relates to improved hook members for
5 hook-and-loop fastening and methods of manufacturing hook
members.

In general, hook-and-loop fasteners comprise two
mating components: a hook member that has upstanding,
hook-type fastener elements, and a loop member that has a
10 surface that provides fibers or fiber loops with which
the hook elements become engaged.

As used here, a "hook member" means a member
having fastener elements whose hooks extend substantially
in a given plane. When of molded form, the stems of
15 these elements are significantly broader in the direction
of their plane of extent than in the thickness direction
at a right angle thereto.

Hook fasteners are often preferred over other
types of fasteners, for instance, those having mushroom-
20 like form, because hook fasteners can provide more secure
engagement with the loops, offer advantages in
manufacturing, etc.

Loop members for hook-and-loop fastening have been
comprised of knitted, woven, and non-woven textiles. A
25 common example of a non-woven textile is known by the
term "spun bonded." It is made by spinning fine
filaments of plastic resin, e.g., polypropylene, and
distributing them in superposed layers. The fibers are
bonded to each other in random orientations, with a fine,
30 low-lying, nappy layer of looped and arched fibers
exposed at the surface of the fabric.

Because non-woven fabrics are inexpensive, they
are desired for use as the loop part of fasteners for low
cost items, particularly disposable products such as
35 diapers, surgical gowns, and sanitary napkins. It is

WO 98/15201

PCT/US97/18004

- 2 -

desirable to provide fastener members useful with very low cost, low loft non-wovens and other low loft fabrics.

Summary of the Invention

One aspect of the invention relates to a fastener member useful for separable engagement with surface fibers of a low-loft, non-woven fabric or the like. The fastener includes a base and multiple rows of molded hook-form fastener elements extending from the base and exposed for engagement with the fabric. Each of the hook form fastener elements comprises a stem portion joined at one end to the base and at least one fiber-engaging hook-form portion joined at the opposite end of the stem portion and having a free end. The hook-form fastener elements lying substantially only in planes aligned with respective rows. At least some of the fastener elements include a fiber-engaging plate portion at the outermost portion of the hook-form portion, which plate portion lies generally parallel to the base. The plate portion provides an overhanging portion in the direction perpendicular to its row that can engage the surface fibers of the fabric.

Certain implementations of this aspect of the invention include one or more of the following features. The fastener member, in certain implementations, provides: a plate portion which has a thickness, in the direction normal to the base, that is less than the height, in the direction normal to the base, of the free end of the hook portion; fastener elements formed of thermoplastic resin, the stem portions of the elements being molded integrally with the base, and the plate portion comprising a post-formed structure formed from the resin of the uppermost portion of the molded fastener element; that substantially all the hook-form portions of the fastener elements in a first row extend in one

WO 98/15201

PCT/US97/18004

- 3 -

direction along the row and substantially all the hook-form portions of the fastener elements in a neighboring second row extend in the opposite direction; that substantially all of the fastener elements include plate portions; that substantially all of the fastener elements in the first row contain a plate portion while substantially all of the elements in the neighboring second row do not; a stem portion which has substantially flat relatively broad sides, a cross-section of each stem portion, taken parallel to the base at the mid-height region of the stem, having a width in the direction of the row and a thickness in the direction perpendicular to the row, the width being about twice the thickness or more; a stem in which the width of the stem tapers from the base to the hook-form portion; a central axis of the stem is inclined, in the direction of the respective row, at a substantially acute angle relative to the base.

Another aspect of the invention relates to a fastener member useful for separable engagement with surface fibers of a low-loft, non-woven fabric or the like. The fastener comprises a base and multiple rows of molded fastener elements extending from the base. Each fastener element comprises a stem portion joined at one end to the base, the stem being inclined, at a substantially acute angle relative to the base in the direction of the respective row of the element, and lying substantially only in planes aligned with its respective row relative to the base, and a fiber-engaging plate portion disposed at the opposite, outermost end of the stem portion, the plate portion extending transversely to the direction of the respective row to form an overhang portion that can engage the surface fibers of the fabric.

Certain implementations of this aspect of the invention include one or more of the following features.

The fastener member, in certain implementations, provides

WO 98/15201

PCT/US97/18004

- 4 -

a cross-section of each stem portion, taken parallel to the base, has a width in the direction of the row and a thickness in the direction perpendicular to the row, the width being substantially greater than the thickness;
5 that substantially all of the fastener elements include plate portions.

In accord with another implementation of the invention, a closure is provided comprising a fastener member as described above and a non-woven fabric engaged
10 therewith, the base of the fastener and the non-woven fabric being under tension in opposite directions such that the fastener elements are subjected to and resist shear forces caused by the tension loading, the tension acting in the direction of the thickness of the stem
15 portion.

Another aspect of the invention relates to a method for making fastener members comprising extruding molten resin and applying the resin to a molding roller having forming cavities around its perimeter. Pressure
20 is applied to the resin to cause the resin to fill the cavities, thereby forming a fastener member preform, the fastener member preform comprising a base and a multiplicity of discrete fastener element preforms integrally molded with and extending from the base at a
25 substantially acute angle, the fastener element preforms aligned in at least one row comprising stem portions with outermost ends lying over the base substantially only in planes aligned with its row. Fastener member preforms are stripped from the molding roller. The outermost
30 portions of at least some of the fastener element preforms are flattened, thereby forming generally plate-shaped portions disposed at the outermost ends and generally parallel to the base and perpendicular to the row.

WO 98/15201

PCT/US97/18004

- 5 -

Certain implementations of this aspect of the invention include one or more of the following features. The method, in certain implementations, provides: the flattening comprises heating the outermost ends of at least some of the fastener element preforms to a temperature that is near the melt temperature of the resin and applying pressure to the outermost ends; the heating and the applying pressure are performed in a single step; the single step comprises passing the fastener member preforms by a heated roller and pressing at least some of the fastener element preforms against the heated roller; the fastener member preforms are formed and the outermost ends of at least some of the preforms are flattened as part of a single, continuous process; the outermost ends of at least some of the fastener element preforms are flattened in a post-processing operation; prior to the flattening, differences in the heights of the fastener element preforms are corrected to ensure generally uniform height; the correcting comprises pressing a knock-down roller against the outermost ends of the fastener element preforms; that substantially all of the fastener elements are flattened; that a product is formed by the method.

In another aspect of the invention, the outermost portions of some fastener elements are farther away from the base, as formed, than the outermost portion of at least some other fastener elements. At least some of the outermost portions farthest away from the base are then flattened, forming generally plate-shaped portions disposed at said outermost ends and generally parallel to the base and perpendicular to the row.

In a preferred embodiment, stripping the preforms from the molding roller causes the fastener members extending in one direction to be deformed to be of

WO 98/15201

PCT/US97/18004

- 6 -

greater height than fastener members in another direction.

Another aspect of the invention relates to a method for improving the engageability of a hook-type fastener member with a non-woven loop-type fastener member. The hook-type fastening member comprising a base and a multiplicity of generally hook-shaped fastener elements integrally molded with and extending from the base in a given direction or in that direction and the opposite direction and lying only in planes parallel with the given direction and perpendicular to the base. The method comprises flattening outermost ends of at least some of the fastener elements to form generally plate-form portions disposed at the distal ends and generally parallel to the base and perpendicular to the planes.

The new hook fastener members are well suited for engagement with low loft non-woven loop members since the outer plate portions of the fastener elements that overhang the sides of the elements are able to slide under and initially engage the surface fibers of the loop member. This feature can improve the level of engagement of the fastener, especially when the fastener elements are subjected to shear forces acting sideways relative to the direction of the plane of the hook elements. The flat-top hook fastener elements, while providing the secure engagement by the hooks, also can avoid skin irritation since the area of contact between the skin and the fastener elements is relatively large. This is of particular value when a hook fastener comes in contact with the skin of babies. Finally, these hook fasteners can be manufactured using conventional hook-member tooling with simple additional post-molding steps.

Other aspects of the invention concern a disposable absorbent garment having first and second opposed longitudinal end portions, and comprises an outer

WO 98/15201

PCT/US97/18004

- 7 -

cover; a body-side liner; an absorbent core located between the outer cover and the body-side liner; a loop member operably associated with the garment; and a fastener member operably associated with the garment for
5 separable engagement with the loop member, the fastener member comprising: a base; and multiple rows of molded hook-form fastener elements extending from the base.

According to one aspect of the invention, the fastener elements are exposed for engagement with the
10 loop member, each of the hook-form fastener elements comprising a stem portion joined at one end to the base and at least one fiber-engaging hook-form portion joined at the opposite end of the stem portion and having a free end, the hook-form fastener elements lying substantially
15 only in planes aligned with respective rows. At least some of the fastener elements include a fiber-engaging plate portion at the outer most portion of the hook-form portion, the plate portion lying generally parallel to the base, the plate portion providing an overhang portion
20 in the direction perpendicular to its row.

Certain implementations of this aspect of the invention have one or more of the following features.

The plate portion has a thickness, in the direction normal to the base, that is less than the
25 height, in the direction normal to the base, of the free end of the hook portion. The stem portion has substantially flat relatively broad sides, a cross-section of each stem portion, taken parallel to the base at the mid-height region of the stem, having a width in
30 the direction of the row, and a thickness in the direction perpendicular to the row, the width being about twice the thickness or more.

Certain advantageous implementations of this aspect of the invention have one or more of the following
35 features. The loop member comprises a nonwoven material.

WO 98/15201

PCT/US97/18004

- 8 -

The loop member is joined to the outer cover in the first opposed longitudinal end section and the fastener member is operably associated with the second opposed longitudinal end section, preferably the garment 25 having a longitudinal axis and wherein the fastener elements are oriented parallel to the longitudinal axis of the garment.

According to another aspect of the invention concerning the disposable absorbent garment, each of the fastener elements comprise a stem portion joined at one end to the base, the stem being inclined at a substantially acute angle relative to the base, in the direction of the respective row of the fastener element and lying substantially only in planes aligned with its respective row. At least some of the elements also comprise a fiber-engaging plate portion disposed at the opposite, outermost end of the stem portion, the plate portion extending transversely to the direction of the respective row to form an overhang portion.

In preferred embodiments of the aspect of the invention, a cross-section of each stem portion, taken parallel to the base, has a width in the direction of the row and a thickness in the direction perpendicular to the row, the width being substantially greater than the thickness.

Certain advantageous implementation of both of these aspects of the invention include that substantially all of the fastener elements include plate portions.

PCT/US97/18004

- 10 -

Embodiments

A preferred embodiment 110 of a hook fastener member, particularly useful on disposable diapers, is shown in Figs. 1, 1a, 1b, 1c, and 2. The hook fastener member consists of a base sheet 112 and multiple parallel rows of integrally molded hook-form fastener elements 114 extending from the base sheet. Although only three rows are shown in several of the figures, it is to be understood that the fastener member may comprise several rows.

As shown in greater detail in Figs. 1a-1c, each fastener element of Fig. 1 has a stem portion 116 of uniform thickness that has flat vertical sides 116a, 116b that extend normal to the plane of the base sheet 112. Joined to the upper end of the stem is a re-entrant, hook-form portion 117 that engages loops or fibers. At the top of the fastener is joined a thin, generally disk-shaped outer plate portion 118 oriented substantially parallel to the base sheet.

The re-entrant hook-form portion curves over and down toward the base sheet from the upper end of the stem portion 116 to define a fiber-retaining recess 119 on the underside of the hook-form portion.

The stem portion in side elevation, as seen in Fig. 1a, tapers outwardly from a wide base to a relatively narrow outer portion in the region of the recess 119. The fastener elements are generally aligned in multiple rows parallel with the flat sides of the individual elements, and the outer plate portion of each fastener element has portions that extend transversely, to overhang the sides 116a, 116b of the fastener element (Figs. 1b, 1c, 2).

In this preferred embodiment, the edge surfaces 123, 125 of the stem portion form angles θ_1 and θ_2 relative to the base sheet, respectively, that are

WO 98/15201

PCT/US97/18004

- 11 -

substantially greater than ninety degrees. Preferably, θ_1 and θ_2 are between about 30 and 160 degrees. More preferably, they are each about 115 degrees and 125 degrees, respectively. Forming the stem portion such
5 that the edges are straight or slant inward allows the preform to be removed more easily from the molding roller
50 because the hook-form portion 117 can pass more easily through the portion of the molding roller in which the stem portion was formed.

10 For use in an important application for the new fastener, in conjunction with non-woven loop members, the fastener elements are generally quite small. Hence, height 130 of the fastener element 114 is preferably
between about 0.005 inch and about 0.030 inch, with about
15 0.0150 inch being most preferred. Furthermore, the base width 126 -- i.e., the width of the stem portion, taken parallel to the base sheet 112 at the level where the stem portion joins the base sheet, disregarding the fillets 128a and 128b -- is preferably between about
20 0.010 inch and about 0.025 inch, with about 0.0170 inch being most preferred.

Furthermore, the fastener elements are provided in relatively high density, for example, from about 500 to about 4,000, alternatively from about 1,000 to 2,500,
25 alternatively from about 1,500 to about 2,000 fastener elements per square inch. For example, as shown in Fig. 2, the elements preferably are spaced apart laterally a distance 135 of about 0.008 inch, and the stem portions 116 preferably have a thickness 136 of about 0.006 lineal
30 inch. This yields a widthwise density of approximately 71 fastener elements per inch. In the lengthwise direction, there are preferably about 24 fastener elements per lineal inch. Hence, there are preferably on the order of 1700 fastener elements per square inch in
35 this preferred embodiment.

WO 98/15201

PCT/US97/18004

- 12 -

A distinctive feature of the hook-form fastener element 114 is the presence of the plate portion 118. This feature contributes to making the hook fastener embodiment 110 particularly useful for engaging the loops of non-woven fabrics in general and, in particular, the low-loft non-woven fibers desired to be used on disposable diapers.

As shown in Figs. 3 and 3a, disposable diapers 10 commonly are made on an assembly line with the fastener tabs 12 extending to the sides, perpendicular to the direction in which the diapers travel. The hook fastener member is provided in large rolls 14 of hook fastener tapes. As explained below, the hook fastener tapes are made using a rotating molding roll in which the hook elements are aligned with the circumference of the roll. As a result of that process, the hook-form fastener elements are aligned along the lengthwise direction of the fastener tapes. For manufacturing efficiency, the hook fastener tapes may be unwound and fed out running parallel to the line of diapers. As each diaper passes the appropriate station, a bonding apparatus 16 such as an ultrasonic welder attaches a patch 18 of hook fastener material to each of the fastener tabs 12. As a result, the hook fastener elements are oriented parallel to the longitudinal axis 20 of the diapers, as shown in greater detail in Fig. 3a. Alternatively, the fastener tabs 12 having hook fastener material 18 attached thereto may be formed in a separate process and the fastener tab attached to the diaper during the diaper manufacturing process. Such a separate process is described, for example, in PCT Application Publication No. WO95/05140 which is hereby incorporated by reference.

When the diaper is put on a baby, it will have the configuration and orientation shown in Fig. 4. Hence, when the fastener tabs 12 are engaged with the mating

WO 98/15201

PCT/US97/18004

- 13 -

non-woven loop member strip 22, the tensile forces S applied to the base of the fastener member and the loop member will act perpendicular to the orientation of the hook-form fastener elements, thereby subjecting the closure to lateral shear forces, as suggested in Fig. 5.

During fastening the fastener tabs 12 will slide slightly relative to the loop member strip 22. This is indicated schematically in Fig. 5, which, with exaggeration for purposes of illustration, shows the edge of the fastener tab 12 at three successive locations 5a, 5b, and 5c. In Fig. 5 there is a "peer-through window" depiction of a single fastener element 114 surrounded by the surface fibers 23 of the non-woven loop member 22, as seen from below the fastener element. As depicted in Figs. 5a, 5b, and 5c, which correspond in Fig. 5 to the locations 5a, 5b, and 5c, respectively, as the fastener element slides slightly, it is shown to intercept a surface fiber 23 which is depicted as anchored to member 12. During the initial sliding action, an overhanging portion of the thin outer plate 118 of the fastener element slides under the low-lying surface fiber 23 (Fig. 5b), as an initial part of the engaging action. As relative motion continues, the fiber is guided by the fillets 120 between the plate portion 118 and the hook-form portion 117 and the stem portion (see Fig. 1b). The fiber 23 is thus guided under the hook-form portion 117 and is secured in the re-entrant fiber-retaining recess 119 to more securely engage the fastener member with the fiber.

In Fig. 5b, the end of the hook element is shown to have been deflected sideways by the force of engagement with the loop member (shown exaggerated for purposes of illustration). This bending, facilitated by the relative thinness (dimension 136) of the element and the off-center loading on the head of the fastener

WO 98/15201

PCT/US97/18004

- 14 -

element is seen to contribute to the effectiveness of the engaging action.

As shown in Fig. 6, a preferred method for making such flat-top hook fastener members entails extruding molten resin into the nip formed between a cooled molding roller 50 and a pressure-applying roller 52, as taught by Fischer, U.S. Patent No. 4,794,028, fully incorporated herein by reference. The cooled molding roller has cavities about its periphery that are configured to produce fastener element preforms 154, which are shown in greater detail in Fig. 6a.

Because the fastener element preforms face in opposite directions, the fastener element preforms in half the columns are oriented along the direction of travel of the tape, and the fastener element preforms in the other half of the columns are oriented opposite to the direction of travel of the tape. The fastener element preforms that are oriented against the direction of travel can leave the mold cavities of the moving roll without significant bending, but the fastener element preforms that are oriented along the direction of travel are bent around the edges of the mold cavities as they are extracted from the cavities. This deforms them slightly, causing them to extend higher from the base sheet and at a slightly steeper angle than the preforms that are oriented along the direction of travel.

For making the two sets of preforms more uniform, the preforms are passed under a knock-down roller 56, the spacing of which, relative to wrap-around roller 57, is adjustable. The knock-down roller pushes the higher and steeper preforms back to the same level, relative to the base sheet, as the level of the preforms that are oriented with the direction of travel of the tape. This leveling will permit more uniform formation of the plate portions 118, discussed below. The knock-down roller 56

WO 98/15201

PCT/US97/18004

- 15 -

is located close to the position where the preforms are withdrawn from the cavities so that the preforms are still slightly soft and permanently deformable when they pass under the knock-down roller and thus retain their new shape.

Alternatively, to form the plate portion on only some of the fastening elements preforms, the knock down roller 56 can be removed. In this manner, the elements oriented against the direction of travel are left in an elongated, higher state and may be deformed to form plate portions 118 without forming plate portions on the elements oriented along the direction of travel.

After the preforms have cooled sufficiently to be strong enough to withstand pressure applied to them without being deformed, the thin, outer plate portions 118 are formed, as at station 58. The plate portions can be formed either in line with the molding process, i.e., as part of a continuous operation, or they can be formed in a separate, post-forming operation at some later time. Hence, the fastener tape is shown as broken in Fig. 6 to indicate this variability.

To form the outer plate portions, the tape of fastener element preforms is passed through gap 60 between a thermo-forming heated roller 62 and a support roller 64, the gap width of which is adjustable. Roller 62 is heated to a selected temperature sufficient to thermally reform the elements. Thus, as the preforms come into contact with the heated thermo-forming roller 62, their outer ends 155 (Fig. 6a) are thermo-formed by the action of the rollers to provide the disk-shaped plate portions 118 of the fastener elements 114.

The selected temperature of roller 62 depends upon the thermal properties of the particular resin being used to make the fastener member and the selected speed of operation. Presently, the shell material of disposable

WO 98/15201

PCT/US97/18004

- 16 -

diapers is often polypropylene. In certain applications, nylon or other materials would also be appropriate. To ensure good bonding when the hook fastener members are attached to the fastener tabs of the diapers 12, the hook fastener member is also preferably made from polypropylene. In this case, the roller 62 is heated to a surface temperature of approximately 350° Fahrenheit, and has operated in a demonstration line at lineal speed of approximately 11 feet per minute (Much higher speeds will be used in production.). The preforms approach the roller 62 nearly tangentially. This results in a temperature at the hook surface which is approximately the same as the melt temperature of the polypropylene resin, and causes the end of the preform to be softened to the point of being permanently deformable under pressure, without being caused to melt to a highly fluid state.

It is, of course, foreseeable that other plastics will be used to form such flat-top hook fastener members. The material selected preferably has a relatively low melt flow index, which is a measure of the viscosity of the resin when it is molten. Resins with fractional melt flow indices, i.e., indices that are less than 1.0, are most preferred, although under certain circumstances and hook designs, resins with melt flow indices as high as 5.0 or 10.0, or even higher, can be used by careful balancing of the steps of the process. The temperature of the roller 62 and the lineal speed through the station 58 are selected to impart a temperature to the hook surface which renders the selected resin moldable. For polypropylene, as noted above, it was found that 350° Fahrenheit was appropriate. Further, additional support rollers and the like may be employed to increase the arc of the roller 62 which the preforms contact, thereby increasing the heating time for a given lineal speed.

WO 98/15201

PCT/US97/18004

- 17 -

The width of the gap 60 between thermo-forming roller and support roller 64 is adjusted to obtain the appropriate height 130 (Fig. 1a) of the final fastener elements, the height 130 in turn being a function of the height of the fastener element preforms. With regard to the amount by which the tops of the hook elements are thermoformed, and therefore with regard to the height 30, it is important that the outer ends not be deformed so much as to impair the geometry of hook-form portion 117 or the ability of the fastener element to engage and retain the fibers of the loop member.

In general, the tops of the elements are thermoformed by an amount to produce an effective overhang of the plate portion, i.e., the amount by which the plate portion extends beyond (overhangs) either side 116a, 116b of the stem portion of the fastener element. Depending upon the conditions of use, it is advantageous for the amount of overhang to fall within the range of 5 to 50% of the thickness of the hook element; in other conditions with the range of 10 to 30%; and in other conditions, within the range of 15 to 25%. In certain preferred instances, the overhang is about 25% of the thickness of the stem portion. Thus, in preferred cases the widthwise dimension 138 of the plate portions (Fig. 2) is approximately 1.5 to 2.0 times the thickness 136 of the stem portion and the vertical thickness 139 of the plate portion 118 is between about 0.2 and 0.4 times the thickness 136 of the stem portion. The lengthwise dimension of the plate portion, in general, will be somewhat longer than the widthwise dimension, and it is generally allowed to be whatever dimension results from thermoforming the plate portion sufficiently to obtain the desired effective sideways overhang and hook height. The thickness of one plate was 0.002 inch and the overhang was 0.003-0.004 inch. A preferred thickness

WO 98/15201

PCT/US97/18004

- 18 -

range is 0.0001 to 0.005 inch, and in certain instances a more preferred range is 0.001 to 0.004 inch.

Finally with regard to the manufacturing process, in order for the plate portions 118 to be substantially parallel to the base of the hook fastener member, it is preferred that the heated roller 62 and support roller 64 rotate at speeds such that their tangential surface velocities substantially match the feed rate of the fastener tape. Otherwise, the plate portions will be dragged by, or will drag along, the heated roller and be deformed.

Another preferred embodiment 210 of a flat-top hook fastening member is shown in Figs. 7, 7a, and 8. This embodiment has a base sheet 212 from which extend a multiplicity of discrete, flat-top fastener elements 214. Each fastener element 214 has a canted stem portion 216, having flat sides similar to sides 116a, 116b of Fig. 1b. These portions are integrally molded with and extend from the base sheet. Each fastener element also has a generally planar, disk-shaped outer plate portion 218 located at the outer end 220 of the stem portion that overhangs the flat sides of the canted stem and a re-entrant hook-form portion 217 depending from the outer plate portion. The plate portion 218 extends generally parallel to the base sheet 212.

As shown in greater detail in Fig. 7a, the general configuration of the stem portion 216 of the fastener elements can be characterized by two parameters. First, it is canted relative to the base 212 in that the surface 222 of the stem portion on the side on which the hook recess is formed forms an acute cant angle α relative to the base. Preferably, cant angle α is between about 30 degrees and about 80 degrees; more preferably, α is between about 40 and 60 degrees, and most preferably, α is about 45 degrees.

WO 98/15201

PCT/US97/18004

- 19 -

The second parameter to characterize the configuration of the stem portion is the base width 226 which, as before, is the width of the stem portion, taken parallel to the base sheet 212 where the stem portion 5 joins the base, disregarding the fillets 228a and 228b. Preferably, the base width is between about 0.010 inch and about 0.018 inch; more preferably, the base width is about 0.014 inch.

Finally, other parameters that characterize the 10 entire fastener element 214 are the height 230 of the fastener element, as measured from the top surface of the base sheet 212 to the top surface of the plate portion 218, and the widthwise dimension 238 of the plate portion. The thickness of the stem portion 236 is 15 preferably the same as for the first embodiment, e.g., about 0.006 inch. Preferably, the height is between about 0.005 inch and about 0.030 inch; more preferably, the height is about 0.015 inch.

As shown in Figs. 7 and 8, the fastener elements 20 214 are arranged on the base sheet 212 with the fastener elements in one column all canted in one direction and the fastener elements in the adjacent column all canted in the opposite direction. The spacing and density of the fastener elements is approximately the same as the 25 spacing and density described above with respect to the first embodiment.

The embodiment of the flat-top hook fastener member of Figs. 7 and 8 is also made by the process shown in Fig. 6. The hook preforms 254 are configured as shown 30 in Fig. 6b which, like the preforms 154 shown in Fig. 6a, are generally of hook shape, although canted relative to the base. Other profiles for a canted hook preform 254 can also be used. See, for example, Fig. 22 of Provost et al., U.S. Patent No. 4,984,339, which is incorporated 35 by reference.

WO 98/15201

PCT/US97/18004

- 20 -

The canted relationship of fasteners elements of Figs. 7 and 9 provide a longer fastener element and a greater degree of off-center loading when subjected to conditions as depicted in Fig. 4 of the preceding embodiment. As a result, under loading conditions depicted in Fig. 4, a greater degree of elastic deflection of the hook end can occur that can increase the fiber-engaging effectiveness of the hook elements.

A third preferred embodiment 310 of a flat-top hook fastener member is shown in Figs. 9, 9a, and 10. This embodiment is similar to the second embodiment 210 discussed above, the outer plate overhanging the flat sides of the canted stem. The primary difference in this embodiment is that the intersection of the canted stem and the outer plate 318 defines a fiber-engaging hook that is not re-entrant. This enables the overhanging plate portion 318 to slide under loop members with extremely low-lying loft. The third embodiment is also manufactured by the method shown in Fig. 6, this time using simple tapered fastener element preforms 354 without re-entrant hooks, as shown in Fig. 6c.

As described above, when the fastener element performs face in opposite directions, the fastener element preforms that are oriented along the direction of travel are bent around the edges of the mold cavities as they are extracted. This causes these preforms to extend higher from the base sheet and at a slightly steeper angle than the preforms that are oriented along the direction of travel.

In certain instances is desirable to form the outer plate portions 118 on only some of the fastener element preforms. This can be achieved, for example, by not passing the fastener element preforms under the knock-down roller 56. Thus, since the fastener element preforms have different heights from the base sheet,

WO 98/15201

PCT/US97/18004

- 21 -

passing the fastener element preforms through gap 60 between the heated roller 62 and support roller 64 will form the disk-shaped plate portions 118 on only those fastener element preforms which extend furthest from the base sheet (those preforms that are oriented along the direction of travel) as shown in Figs. 11 and 12. For some applications, having some of the fastener element preforms possess the disk-shaped plate portions 118 and others not possess the plate portions provides for a more satisfactory balance of fastening properties (such as a desired balance of peel and shear properties). In other embodiments the fastener element preforms are formed to have different heights from the base sheet independent of their orientation during manufacture. This is accomplished through the use of mold cavities having different depths during formation of the preforms. With such preforms, in one embodiment flat tops are provided only on those preforms having the greatest height. Forming the fastener element preforms to have different heights from the base sheet in some instance allows greater control over the percentage of elements that are "flat topped." It is possible to form fastener element preforms with two, three or more different heights from the base sheet.

Other embodiments are within the scope of the following claims.

WO 98/15201

PCT/US97/18004

- 22 -

What is claimed is:

1. A fastener member comprising
a base, and
multiple rows of molded hook-form fastener
5 elements extending from said base and exposed for
engagement with a fabric, each said hook-form fastener
element comprising a stem portion joined at one end to
said base and at least one fiber-engaging hook-form
portion joined at the opposite end of said stem portion
10 and having a free end,
said hook-form fastener elements lying
substantially only in planes aligned with respective
rows,
at least some of said fastener elements including
15 a fiber-engaging plate portion at the outermost portion
of said hook-form portion, said plate portion lying
generally parallel to said base,
said plate portion providing an overhang portion
in the direction perpendicular to its row.
20 2. The fastener member of claim 1 wherein said
plate portion has a thickness, in the direction normal to
said base, that is less than the height, in the direction
normal to said base, of the free end of said hook
portion.
25 3. The fastener member of claim 1 wherein said
fastener elements are formed of thermoplastic resin, said
stem portions of said elements being molded integrally
with said base, and said plate portion comprising a post-
formed structure formed from the resin of said uppermost
30 portion of said molded fastener element.

WO 98/15201

PCT/US97/18004

- 23 -

4. The fastener member of claim 1 wherein substantially all the hook-form portions of the fastener elements in a first row extend in one direction along said row and substantially all the hook-form portions of the fastener elements in a neighboring second row extend in the opposite direction.

5. The fastener member of claim 4 in which substantially all of the fastener elements in said first row include a said plate portion, and substantially all of the fastener elements in said neighboring second row do not include a said plate portion.

6. The fastener member of claim 1 wherein said stem portion has substantially flat relatively broad sides, a cross-section of each said stem portion, taken parallel to said base at the mid-height region of the stem, having a width in the direction of said row and a thickness in the direction perpendicular to said row, said width being about twice said thickness or more.

7. The fastener member of claim 6 wherein the width of said stem tapers from said base to said hook-form portion.

8. The fastener member of claim 1 wherein a central axis of said stem is inclined, in the direction of the respective row, at a substantially acute angle relative to said base.

9. The fastener member of claim 1 in which substantially all of said fastener elements include said plate portions.

WO 98/15201

PCT/US97/18004

- 24 -

10. A fastener member comprising
a base, and
multiple rows of molded fastener elements
extending from said base, each said fastener element
5 comprising a stem portion joined at one end to said base,
said stem being inclined at a substantially acute angle
relative to the base, in the direction of the respective
row of said fastener element and lying substantially only
in planes aligned with its respective row, and
10 fiber-engaging plate portions disposed at the
opposite, outermost end of the stem portions of at least
some of the tallest of said fastener elements, said plate
portions extending transversely to the direction of the
respective row to form overhang portions.
- 15 11. The fastener member of claim 10 in which
substantially all of said fastener elements include said
plate portions.
12. The fastener member of claim 10 wherein a
cross-section of each said stem portion, taken parallel
20 to said base, has a width in the direction of said row
and a thickness in the direction perpendicular to said
row, said width being substantially greater than said
thickness.
13. A closure comprising the fastener member of
25 claim 6 or claim 12 and a non-woven fabric engaged
therewith, the base of said fastener and said non-woven
fabric being under tension in opposite directions such
that said fastener elements are subjected to and resist
shear forces caused by said tension loading, the tension
30 acting in the direction of the thickness of said stem
portion.

WO 98/15201

PCT/US97/18004

- 25 -

14. A method for making fastener members comprising:

extruding molten resin and applying said resin to a molding roller having forming cavities around its
5 perimeter;

applying pressure to said resin to cause said resin to fill said cavities, thereby forming a fastener member preform, said fastener member preform comprising a base and a multiplicity of discrete fastener element
10 preforms aligned in at least one row, integrally molded with and extending from said base at a substantially acute angle, said fastener element preforms comprising stem portions with outermost ends lying over said base substantially only in planes aligned with its row;

15 stripping said fastener member preforms from said molding roller; and

flattening said outermost portions of at least some of said fastener element preforms, thereby forming generally plate-shaped portions disposed at said
20 outermost ends and generally parallel to said base and perpendicular to the row.

15. The method of claim 14 wherein said flattening comprises heating said outermost ends of at least some of said fastener element preforms to a
25 temperature that is near the melt temperature of said resin and applying pressure to said outermost ends.

16. The method of claim 15 wherein said heating and said applying pressure are performed in a single step.

30 17. The method of claim 16 wherein said single step comprises passing said fastener member preforms by a

WO 98/15201

PCT/US97/18004

- 26 -

heated roller and pressing at least some of said fastener element preforms against said heated roller.

18. The method of claim 14 wherein said fastener member preforms are formed and said outermost ends of at least some of said preforms are flattened as part of a single, continuous process.

19. The method of claim 14 wherein said outermost ends of at least some of said fastener element preforms are flattened in a post-processing operation.

20. The method of claim 14 further comprising, prior to said flattening, correcting differences in the heights of said fastener element preforms to ensure generally uniform height.

21. The method of claim 20 wherein said correcting comprises pressing a knock-down roller against said outermost ends of said fastener element preforms.

22. A method for making fastener members comprising:

extruding molten resin and applying said resin to a molding roller having forming cavities around its perimeter;

applying pressure to said resin to cause said resin to fill said cavities, thereby forming a fastener member preform, said fastener member preform comprising a base and a multiplicity of discrete fastener element preforms aligned in at least one row, integrally molded with and extending from said base at a substantially acute angle, said fastener element preforms comprising stem portions with outermost ends lying over said base substantially only in planes aligned with its row, the

WO 98/15201

PCT/US97/18004

- 27 -

outermost portions of some fastener elements being farther away from the base, as formed, than the outermost portions of at least some of other fastener elements;

stripping said fastener member preforms from said
5 molding roller; and

flattening at least some of said outermost portions farthest away from said base, thereby forming generally plate-shaped portions disposed at said outermost ends and generally parallel to said base and
10 perpendicular to the row.

23. The preforms method of claim 22 in which stripping said fastener member from said molding roller causes the fastener members extending in one direction to be deformed to be of greater height than fastener members
15 extending in another direction.

24. The method of claim 14 which comprises flattening said outermost portion of substantially all of said fastener element preforms.

25. The product formed by the method of claim 11
20 or claim 24.

26. A method for improving the engageability of a hook-type fastener member with a non-woven loop-type fastener member, said hook-type fastening member comprising a base and a multiplicity of generally hook-
25 shaped fastener elements integrally molded with and extending from said base in a given direction or in that direction and the opposite direction, and lying only in planes parallel with the given direction and perpendicular to the base, said method comprising
30 flattening outermost ends of at least some of said fastener elements to form generally plate-form portions

WO 98/15201

PCT/US97/18004

- 28 -

disposed at said distal ends and generally parallel to said base and perpendicular to the planes.

27. A disposable absorbent garment having first and second opposed longitudinal end portions, said
5 garment comprising:
 an outer cover;
 a body-side liner;
 an absorbent core located between said outer
cover and said body-side liner;
10 a loop member operably associated with said
garment; and
 a fastener member operably associated with
said garment for separable engagement with said loop
member, said fastener member comprising:
15 a base; and
 multiple rows of molded hook-form fastener
elements extending from said base and exposed for
engagement with said loop member, each said hook-form
fastener element comprising a stem portion joined at one
20 end to said base and at least one fiber-engaging hook-
form portion joined at the opposite end of said stem
portion and having a free end,
 said hook-form fastener elements lying
substantially only in planes aligned with respective
25 rows,
 at least some of said fastener elements
including a fiber-engaging plate portion at the outer
most portion of said hook-form portion, said plate
portion lying generally parallel to said base,
30 said plate portion providing an overhang
portion in the direction perpendicular to its row.

28. The garment of claim 27 wherein said plate
portion has a thickness, in the direction normal to said

WO 98/15201

PCT/US97/18004

- 29 -

base, that is less than the height, in the direction normal to said base, of the free end of said hook portion.

29. The garment of claim 27 wherein said stem
5 portion has substantially flat relatively broad sides, a cross-section of each said stem portion, taken parallel to said base at the mid-height region of the stem, having a width in the direction of said row and a thickness in the direction perpendicular to said row, said width being
10 about twice said thickness or more.

30. The garment of claim 27 wherein said loop member comprises a nonwoven material.

31. The garment of claim 27 wherein said loop
member is joined to the outer cover in said first opposed
15 longitudinal end section and said fastener member is operably associated with said second opposed longitudinal end section.

32. The garment of claim 31 having a longitudinal axis wherein the fastener elements are oriented parallel
20 to the longitudinal axis of the garment.

33. A disposable absorbent garment having first and second opposed longitudinal end portions, said garment comprising:
25 an outer cover;
a body-side liner;
an absorbent core located between said outer cover and said body-side liner;
a loop member operably associated with said garment; and

WO 98/15201

PCT/US97/18004

- 30 -

a fastener member operably associated with said garment for separable engagement with said loop member, said fastener member comprising:

a base; and

- 5 multiple rows of molded fastener elements extending from said base, each said fastener element comprising a stem portion joined at one end to said base, said stem being inclined at a substantially acute angle relative to the base, in the direction of the respective
- 10 row of said fastener element and lying substantially only in planes aligned with its respective row, and
- fiber-engaging plate portions disposed at the opposite, outermost end of the stem portions of at least some of said plate portions extending transversely to the
- 15 direction of the respective row to form overhang portions.

34. The garment of claim 33 wherein a cross-section of each said stem portion, taken parallel to said base, has a width in the direction of said row and a
- 20 thickness in the direction perpendicular to said row, said width being substantially greater than said thickness.

35. The garment of claim 33 wherein said loop member comprises a nonwoven material.

- 25 36. The garment of claim 33 wherein said loop member is joined to the outer cover in said first opposed longitudinal end section and said fastener member is operably associated with said second opposed longitudinal end section.
